ABSTRACT

This study examined gender issues in public education, focusing on the Edina Public Schools, Minnesota. Data gathered from district, state, national, and international sources included student enrollment, student participation in school or district programs, grades from school report cards, standardized test scores, and perceptions and attitudes from surveys on gender similarity and differences. Statewide and national data from the NAEP were also collected. Overall, gender differences in perspectives of environment and student behavior took hold during adolescence. Males and females had unique, equally painful problems. Three times as many boys as girls were in special education. Language arts and social studies were a more female province, while computer science, economics, and sciences were a male province. Girls were more engaged in school and classroom learning, worked harder, and received higher grades and more recognition than boys. Boys were much more likely to be suspended, had more incidents of ill-disciplined and risk taking behaviors, and were more impulsive. Few differences were found in developmental cognitive abilities in the verbal skills. Average academic achievement was similar for boys and girls. However, a disproportionate number of boys performed at the lowestachieving level, and a disproportionate number of girls performed at or above the highest-achieving level. (Contains approximately 180 references.) (SM)

Paper for the presentation of the American Education Research Association Annual Conference at Chicago, April 2003

In today's highly charged national focus on how to improve student learning achievement and school performance, understanding the differences between male and female students is an important element for increasing all students' successes. Over the past three decades, educators, researchers, and policy-makers have engaged in a debate about gender equity in education. Although progress has been made in achievement and participation in programs and services for girls and boys, understanding of gender differences and its relationship to student learning outcomes has not fully developed yet.

Researchers and educators in Edina Public Schools became aware of apparent differences in male and female student performance in school and sought to explore the gender issue and its implications for the theory and practice of teaching and learning. Hence, an objective was developed for the 2001-02 school year aimed at learning more about teaching and learning practice and probable gender impact. To this end, the Edina Public Schools formed a Gender Task Force Committee to conduct a study and examine gender differences at all age.

This study mainly focuses on collecting evidence of gender difference and its impact on student learning. In particular, the following research questions guided the analyses, considerations and implications. (1) Are there gender differences that have an influence on student development and learning? (2) Can we find hard evidence about gender differences in the classroom and the school? (3) What are the perceived and real learning differences or developmental differences between males and females? (4) Does the school enterprise include behaviors, expectations and systems that appear to impact student learning and growth? Can a relationship between these behaviors and expectations and an impact on gender differences be established? (5) Is student earning impacted by the specific behavior and actions of adults and other students during the schooling process? (6) How can we ensure that the education system customizes the instruction delivered in the classroom and school at large to best meet the needs of both boys and girls?

The study reviewed theories and findings on gender research and sought to better understanding a foundation of best practice in primary K-12 public and private school settings nationally. Next, this study collected evidence of gender similarities and differences in the Edina Public Schools. Finally, this study analyzed and synthesized the comprehensive data collected and established considerations and implications for classrooms and schools to regard as fundamental challenges in teaching and learning practice. Findings of this research were reported to the Edina School

3

Board of Education and reported in the local and state newspapers¹. In addition, these findings drew much attention among Minnesota communities. Presenting this study in AERA, we hope others can be benefit from our insights and learn from our errors. In addition, we hope better understanding gender differences will help plan toward a more effective set-of-solutions for improving student performance.

Literature Review

Literature and research suggest that boys and girls, over time, may not fully benefit from our educational system and its instructional delivery. Also, boys and girls have different learning and developmental needs. In the 1970s, Gilligan, the Sadkers, and the American Association of University of Women began the gender research and found a great deal of bias against females in adult and child communities. During the two decades since 1970, the focus of work on gender published in the field of education was on girls. Researchers demonstrated that career expectations and subject choices were structured along traditional gender lines, to the disadvantage of female. The hidden curriculum contributed to the reinforcement of sex roles, and aspects of the formal curriculum reinforced masculine notions of subjects such as science and mathematics. This perspective was promoted in schools of education. Schools were urged to adopt equal opportunity policies in an attempt to confront these issues, new textbooks sought to avoid gender bias, and some steps, such as the Girls Into Science and Technology Project, were taken to make science more attractive to girls.

In the 1990s, British and Australian educators were ahead of American educators in confronting and specifically addressing the problem of male underachievement. Britain researchers found that girls were consistently outperforming boys in achievement across the range of subjects, particularly in English, the humanities and foreign languages over several years from the national high school graduation examinations (General Certificate of Secondary Education). Vigorous debate has taken place in Britain, searching for reasons for boys' lower levels of achievement, and exploring ways in which the gap can be narrowed. Research has been carried out at a number of levels to explain the failure of boys to achieve at the same level as girls, including teacher-student interaction, curriculum content, gender images of subjects, modes of assessment, single-sex schooling, labor market changes, and concepts of masculinity. Also, Australia educators focused on masculinity and followed up the "boys and relationships" theme, as is evidenced by increasing educational press coverage and demands for consultancy.

In the United States, data from the Condition of Education by the U.S. Department of Education (1995) and The American Teacher 1997: Examining Gender Issues in Public Schools by the Metropolitan Life Insurance Company (1997) started to show boys on average are a year and a half behind girls in reading and writing; they are less committed to school and less likely to go to college. In the same year, college fulltime enrollment was 45 percent male and 55 percent female. The U.S. Department of Education predicted that the ratio of boys' entry into college would continue to worse. Kipnis (1999) examined the lives of boys at risk and suggests that more boys than girls have troubles socially, academically, and emotionally in school. Summers (1999) cited numerous statistical numbers and claims that American girls are thriving in school and American boys are the "second sex." Furthermore, Gurian (2001) provided scientific evidences and documented many biological gender differences that influence learning and shows that educators must change the classroom strategy for gender differences.

As limitations of scope of research, these studies did not provide a comprehensive picture of gender differences with multiple facets, such as achievement, intellect, motivation, interest, social and emotional development, as well as school and classroom environment. Furthermore, those studies did not explain the causes of gender differences, nor provide appropriate recommendations to improve education policies and strategies that can develop educational systems that better serve all students.

The Edina Public Schools conducted this gender research to find and collect sufficient evidence to examine whether there are gender differences in learning and development in multiple facets such as achievement, intellect, psychology, behavior, social and emotion development, and school and classroom environment. In addition, this study intends to explore the reasons for the gender differences and develop teaching strategies and school-wide and district-wide reform strategies to address these differences in the classroom to meet different needs of boys and girls.

Methodology

In order to analyze the gender differences clearly and deeply, a Gender Task Force Research Committee was formed. Members of this group were represented by grade, school, administrator/teacher, and gender. This group met every month to monitor the progress of the gender research. In the beginning of the research, this group defined a comprehensive data set to

be gathered from the district, the state, national and international sources. Comprehensive data from K-12 grades were gathered and assembled from a variety of sources including enrollment, student participation in school or district programs, student grades from school report cards, standardized test scores, perceptions and attitudes from surveys on gender similarity and differences in the Edina Public Schools. Also, statewide data and national data (NAEP) were used to present a more comprehensive comparison. This group examined all data and formed plausible explanations, and in-depth analyses. Finally, this group provided instructional and curriculum recommendations that educators can use to enhance the success of all students.

In data collection and analysis, entire student population was used for data collection, including enrollment, participation, academic records, and survey data. Due to the lack of a uniform format and the manual entry nature of the elementary report card system, a stratified random-selected sample was used to collect the elementary report cards for analyzing grades by gender.

In order to examine patterns and draw valid findings from these data, all data were tracked back for four years when possible, and broken down by gender for analysis. Descriptive statistics were derived using the traditional statistical analyses. T-tests or F-tests were conducted to examine if the gender differences are statistically significant.

Results and Analyses

Student Enrollment and Participation

Four years' enrollment data were collected, summarized and examined by grade and gender. Student participation in school and district programs such as special education services, remedial or intervention programs, gifted education services program², were collected and analyzed. By conducting gender analyses in these programs, the study is intended to find whether these programs meet both male and female student needs.

Table 1 shows the differences in student enrollment in the Edina Public Schools by gender and by grade. The overall enrollment trend over the last four years shows the enrollment of males and females was approximately the same over the four years, although a few statistically significant differences were found in some grades and some schools.

Table 2 presents data by gender about students who are receiving special education services and students who were identified for taking medication at school for Attention Deficit Hyperactivity Disorder (ADHD). The results reveal considerable gender differences among students receiving special education services and ADHD. Across all grades, males were disproportionally represented.

Tables 3 and 4 present data by gender for low-achieving students who received remedial and intervention services or participated in alternative programs. Students who scored below 40 on the national percentile ranks in the standardized tests or were recommended by classroom teachers were qualified for the Success Center Program. The data reveal a tendency for males to outnumber females among low-achieving students in most elementary grades and in all types of secondary school alternative programs.

The analysis of the gender composition of enrollment and participation in the school and district educational programs showed that, in general, Edina students were gender balanced in general enrollment and gifted education services program. However, males were over-represented in special educational services, ADHD, remedial or intervention programs, and alternative programs.

Academic Performance and Achievement

Data, including course grades, class ranks, honor rolls, awards, national Merit Scholar recipients, standardized achievement test results, cognitive ability test results, student participation and test results in Advanced Placement programs (AP), were reported and analyzed. This analysis is intended to examine if both males and females have benefited and learned from the Edina Public Schools educational programs and if, in fact, males and females have different learning preferences.

Table 6 shows the number and percentage of students by gender in grades 6 through 12 who are in the top class ranks in 2000-01 and who are on the A Honor Roll. The results reveal significant gender differences in their course grades. Across the grades, females were disproportionally represented among high-achieving students.

Note: \triangle = Gender difference statistically significant at .05 level.

Table 7 shows that number of students who received school or district awards for academic performance or participation in activities. At the elementary school level, no significant difference was shown between boys and girls. At the secondary level, however, the number of females who received recognition and awards for their academic performance from the school, district and the nation was significantly higher than males.

Table 8 shows the number and percentage of students who were the National Merit Scholar recipients by gender over the last 12 years. The results reveal a slight tendency for females to outnumber males among Merit Scholar recipients over the last 12 years.

Table 13 shows numbers and percentages of students who enrolled in Advanced Placement Programs⁹ (AP) as well as basic and resource courses. The results reveal the pattern of males and females that attended high-academic AP courses and low academic resource or basic courses. It is interesting to note that the pattern for gender differences is by subjects. As shown in Table 13, females exhibited significantly higher enrollments in social studies and language AP courses, while males exhibited significantly higher enrollments in mathematics, science, computer and economics AP courses. Also, the results show that significantly more males selected and attended basic or resources courses.

Table 14 shows the number of students who participated in AP tests by gender. The results reveal that more females participated in AP tests and proportionally received a score of 3 or above in grades 9 through 11. At grade 12, more males received a score of 3 or above.

Table 16 presents all grade 10 student PLAN test results over the last four years. As shown in this table, females outperformed males in English and reading, while there were few differences between males and females in mathematics and science achievement. Table 17 presents data for grade 12 students who took ACT for college purposes over the last four years. In these results, based on a volunteer sample, females had the advantage in English, while males outperformed females in both mathematics and science.

Tables 18 and 19 present PSAT¹⁰ and SAT¹¹ results. Generally, only high-achieving students are likely to take these tests for National Merit Scholar recognition or college specific requirements. Results show that males outperformed females in mathematics and females outperformed males in writing over the four years in PSAT tests at grade 11. At grade 12, high-achieving males were more likely to outperform females in both verbal and mathematics on SAT tests.

Table 20 presents student grades from school year 2000-2001 Edina elementary report cards. Grades in Reading, Listening and Speaking, Writing, and Mathematics were reported. In each subject, small content categories were averaged and totaled. For example, there are three categories under reading: Demonstrates comprehension, Reads independently, and Applies skills. After totaling small content categories, the scale for reporting results ranges from a low of 3 to a high of 12.

As the tables show, in general, few significant gender differences exist between male and females in student grades in Reading, Writing, and Mathematics as well as in work habits at the elementary school level. Girls at grades 1-5 received significantly higher grades than boys in areas, Listening and Speaking.

Note: \triangle = Gender difference statistically significant at .05 level.

The results presented in this section suggest that few significant gender differences existed in student grades in reading, writing and mathematics at the elementary school level. There did appear to be differences noted in areas of Listening and Speaking where boys were scored lower than girls. At the secondary level, females tend to perform better and receive more recognition in classroom-based indicators than males. In standardized tests, females tend to perform higher than males in reading and writing tests, while males tend to perform higher than females in mathematics. The Cognitive Ability Tests results, however, suggest little gender difference in verbal and nonverbal abilities at grades 2, 4 and 7, with a number of significant differences favoring boys in grades 4 and 7 in quantitative abilities.

Males and females show different tendencies in selecting AP and other courses at the high school. More males selected to attend mathematics, science, computer and economics AP courses, while more females selected to attend language and social studies AP courses. More females took AP tests at Grades 10 and 11 and received scores of 3 or higher on the 1-5 point scale. More males took AP tests at Grade 12 and received scores of 3 or higher. More males were enrolled in remedial and intervention subjects and more males took part in alternative learning classes.

Analysis also shows that different distributions in academic achievement exist from males to females. More males achieved at the bottom quartile and more females, in general, achieved at or above the top quartile. Although the number of male high-achievers was not as high as that of females, the average achievement of the male high-achievers, specifically in grades 11 and 12 in mathematics, was significantly higher than that of the female high-achievers.

Student Perceptions and Opinions

Data were collected from a variety of student opinion surveys: Minnesota Student Survey¹² in 1995, 1998 and 2001, the Edina Public Schools Student Opinion Survey¹⁴ in 2001, the Developmental Assets Survey¹³ in 1999 as well as the Edina Five Years After High School Survey. Analysis in this section examines if both genders benefited from their school learning environment and acquired developmental assets and behaviors.

Table 21 gathers information about student perceptions of their grades at school from the Search Institute Survey in 1999 and the Minnesota Student Health Survey in 1995, 1998, and 2001, respectively. The Minnesota Student Survey investigates students in grades 6, 9 and 12, while the Developmental Assets Survey investigates students in grades 6 through 12. Data presented here used results from the Developmental Assets Surveys in grades 6, 9, and 12 to keep a consistent and valid comparison with the results from the Minnesota Student Survey. In both survey instruments, students were asked if they most often received grades of A, A and B, B and C, C and D. As shown in Table 21, significantly more females reported that they most often received A or A and B than males in grades 6, 9 and 12 over the four years.

Table 21 Students Who Report That They Most Often Received Grades of A or A and B

		Grade 6			Grade 9.	_		Grade 12

2001	▲ 84%	73%	11%	▲ 80%	60%	20%	▲ 74%	61%	13%

Note: \triangle = Gender difference statistically significant at .05 level. Sources:

- 1. Developmental Assets: A Profile of Your Youth, Edina Public Schools. The Search Institute Survey 1999.
- The Minnesota Student Health Survey, Edina Public Schools results, 1995, 1998 and 2001.

Since homework assignments can reinforce in-class learning and provide students with additional learning activities, the amount of time students devote to their homework is thought to have a major impact on what is learned. For example, research in learning mathematics has shown that

21

students who spend more time on homework are more likely to develop mathematics ideas, and perform at higher levels on tests that measure mathematical concepts.

Tables 22 and 23 summarize information about the amount of time males and females reported doing their homework. Table 22 reports results from the Edina Student Opinion Survey in 2001. Table 23 reports results from the Search Institute Survey in 1999 and from the Minnesota Student Health Survey in 1995, 1998 and 2001, respectively. On average, females and males in grades 1 through 7 spent similar amounts of time doing homework. In grades 8 through 12, significantly more females reported spending at least one hour doing homework daily than males.

Parallel to the results shown in Table 22, results in Table 23 show that females in grade 9 and 12 outnumbered males in spending three hours doing homework daily across four years. The exception was grade 6 where there was less gender differences regarding homework time. Table 24 presents percentages of grades 6, 9 and 12 students who reported they like school. Generally, more females than males reported that they like school.

Notes

- 1. = Gender difference statistically significant at .05 level.
- 2. The survey asked students whether they spend 0 hour, half hour, 1 hour, or 2 hours or more doing homework daily. The results combined students' responses. At the elementary level, data were from all students who reported spending a half-hour or more. At the secondary level, data were from all students who reported spending at least one hour doing homework daily.

Table 25 presents the results from the Edina Student Opinion Survey in 2001 about the percentage of students at grades 1 through 5 who reported they were encouraged at school. The results show that there were few differences in reporting encouragement at school in most of grades. A few significant differences that favored females over males were observed.

Table 26 presents the results from the Developmental Asset Survey in 1999 about the percentage of students at grades 6 through 12 who reported they are encouraged at school. Results on this table show more statistically significant differences comparable to the results in Table 25. All of the statistically significant differences favored females. More females at the secondary level reported they were encouraged at school.

Sources: Developmental Assets: A Profile of Your Youth, Edina Public Schools. The Search Institute Survey, 1999.

Tables 27 and 28 report survey results from students who indicated that if they spend at least one hour doing the following activities each week:

- 1. practicing or taking lessons in music, art, drama, or dance, after school or on weekends,
- going to programs, groups, or services at a church, synagogue, mosque, or other religious or spiritual places;
- 3. helping other people without getting paid such as helping out at a hospital, daycare center, food shelf, youth program, community service agency, or doing volunteer work
- 4. reading just for fun (not part of schoolwork).
- 5. playing computers or video games.

The original survey questions asked if students spend 0, 1, 2, 3-5, 6-10, or 11 hours or more on the activities mentioned above. In the tables, student responses were combined from "1 hour" to "11 hours or more" and reported as "spent at least one hour." Results from both tables reveal that significantly more females, specifically females in grades 9 and 12, spend their time on participating in lessons or activities in music, art, drama or dance activities, church activities, or reading for fun. Although a few gender differences between grade 6 males and females were found regarding time spent on music, art, or church activities, generally gender differences were small or negligible for grade 6 students over the years studied.

The 2001 Minnesota Student Survey added a question that investigated the time students spent on computer games or video games. The results of this survey show that significantly more males reported that they spend at least one hour playing computer or video games than females on a weekly basis. Table 28 confirms the results in Table 27 that significantly more females reported they spend at least one hour on reading for pleasure.

There is growing concern in the United States about the increase in negative and potentially life-threatening behaviors among our young people coupled with a decrease in positive, health-promoting behaviors. In this report, information about Edina student involvement in risk-taking (e.g., violence, chemical use, etc.) behaviors were presented and analyzed by gender. This analysis is intended to examine what percentage of Edina males and females are reporting risk-taking behaviors and what gender differences exist in general and across grade levels.

Table 29 shows the percentage of males and females that reported that they were hurt by violence or experienced an unfriendly environment. Table 29 reveals that significantly more males at grades 6, 9 and 12 reported that they were victims of violence at grades 6, 9 and 12 during the last 12 months.

Table 30 presents the percentage of males and females who reported that they had engaged in some anti-social behaviors in the last 12 months, such as damaging or destroying property, hitting or beating up another person or engaging in dangerous behaviors. The results show an extreme pattern. Males were disproportionately represented among those anti-social behaviors. The exception was the information obtained from the new question about thinking about killing yourself in the 2001 survey. The percentages of responses show more females in grades 9 and 12 who felt depressed and thought about killing themselves. National data would support this trend, however, national data would also reveal a higher percentage of males than female succeeded at suicide.

Table 31 presents the percentage of surveyed males and females who reported that they never engaged in risk-taking behaviors related specifically to alcohol, tobacco, and/or other drug use. The results reveal a slight tendency for the gender gaps to be somewhat larger for older students. That is, risk-taking behaviors increased with grade for both genders, but sometimes the increase for males exceeded the increase for females, resulting in a widening of the gender gap. Specifically, significantly fewer females were involved in using drugs, binge drinking and using tobacco products by grade 12.

Note: \triangle = Gender difference statistically significant at .05 level.

In summary, results in this section suggest that females were better engaged in school than males. Females tended use their time more constructively in activities such as doing homework, participating in music, arts, church, or volunteer work, etc. Males devoted more time to computer or video games. Males were engaged in more risk-taking behaviors such as violence or chemical use than females. Also, more males appeared to be victims of violence than females.

Analyses of these data across grades revealed a tendency for gender gaps in constructively using time and risk-taking behaviors starting at grade 9 and higher. In general, student risk-taking behaviors increased with each grade for both genders, but sometimes the increase for males exceeded the increase for females, resulting in a widening of the gender gap by grade 12.

Statewide and National Data

In order to examine whether gender differences in school or learning are merely a local issue or a statewide, nationwide or international phenomena, data were collected from Minnesota, and the United States.

Table 33 presents the number and percentage of high school student's graduation and dropout statewide by gender. The results show that more females graduated from Minnesota high schools and more males dropped out of Minnesota schools.

Table 33
Four-year High School Completion and Dropout Rates

Table 34 presents Minnesota student average results from the Minnesota Comprehensive Assessments (MCA) for grades 3 and 5 and the Minnesota Basic Standards Tests (BST) for grade 8. This table reports percentages of students who met the Minnesota High Standards on the MCA (percentages of students at "Above Grade Level" or "Advanced Level) and who met the Minnesota Basic Standards on the BST. The results reveal that females outperformed males in reading and writing, while males achieved slightly higher than females in mathematics. However, the gender gap in reading and writing was wider than the gender gap in mathematics.

Table 35 presents by gender the average reading, writing, mathematics and science achievement for grades 4, 8, and 12 nationally in 1992, 1994, 1998 and 2000. As shown in Table 35, the gender differences varied depending upon the learning subjects or areas. The gender differences in reading and writing reflected advantages for females, while in science, the gender differences observed favored males. Males had significantly higher average mathematical achievement than females at grade 4 and grade 12. In grade 8, females and males had similar achievement in mathematics.

Table 36 shows the percentages of males and females nationally that had completed high school and high school completers with some college from 1971 to 1998. As shown in Table 36, before 1980, the educational attainment of males was higher than that of females at all educational levels. In the early 1980s, females equaled males, and by the late 1980s, females surpassed males in terms of completion of a high school education and college attendance. In 1998, females by age 25 to 29 were somewhat more likely than males to have graduated from high school (90 percent of females versus 87 percent of males) and enroll in college (68 percent of females versus 63 percent of males).

1998	86.6	89.6	88.1	63.0	68.1	65.6		

Note: The Current Population Survey (CPS) questions used to obtain educational attainment were changed in 1992. From 1992 to 1998, high school completers includes those who have a high school diploma or an equivalency certificate. From 1971 to 1991, high school completers are individuals who have completed 4 years of high school or more (but may not have a diploma or equivalency certificate.) Included in total but not shown separately are other racial/ethnic groups.

Source: U.S. Department of Commerce, Bureau of the Census, March Current Population Surveys.

Results suggest that in Edina, Minnesota and the United States, females tended to perform significantly higher than males in reading and writing while males tended to perform significantly higher than females in mathematics and science. However, the gender differences in reading and writing for males appeared greater than the gender differences in mathematics for females. It is important to note that after 1998

more females completed high school education and attended college than males based on data from the United State Department of Commerce. The data indicate a change in the trend for the educational attainment of males to be higher than that for females. Now, females exceed males in acquiring education at all levels.

Discussion

Data mentioned above provide preliminary observations, evidence and useful insights into gender considerations in the Edina Public Schools. Findings from data provide important questions for educators regarding pedagogical theories and practice. How can we develop appropriate policies that provide opportunities for both boys and girls in our schools? How can educators develop teaching strategies that promote student potential? How can we learn and implement educational practices that empower and sensitize both boys and girls?

Several years ago, British and Australian educators addressed the gender differences, searched for the reasons for the differences and explored ways for both genders to access equal opportunity in learning. Research has been conducted at a number of levels to explain the gender differences in academics. Issues, such as teacher-student interaction, curriculum content, and the gender image of subjects, modes of assessment, single-sex schooling, labor market changes, and the concepts of masculinity, in particular, were examined. It seems that educators may find it worthwhile to know more about gender and learning implications for schools and classrooms.

Gendered Adolescence

Data results suggest gender differences in perspectives of environment and student behaviors, including constructive and risk-taking behaviors, appeared to take hold at adolescence (grades 8 and 9).

Adolescence is a naturally occurring time of transition; a period when changes happen that affect the experience of self and relationships with others. Thus, adolescence is a time of epistemological crisis; an age when issues of interpretation come to the fore.

Research shows that males and females each have their own equally painful sufferings. Girls tend to suffer the majority of depression or eating disorders. Boys tend to be moody and aggressive. Boys seek competitive sports, or any physical or motor activities through which they can release tension, take risks and show competitive prowess.

Often adolescent boys and girls seem tough, but they need an emotional center and secure base now more than ever before. The key to helping them navigate adolescence is not to leave them alone through the

3 (

process, but rather be deliberate about finding directions and options that channel their energy positively. This supports the attention that schools give to individual and group counseling and the focus on personal, social, and emotional characteristics that many school curriculums adopt.

Gendered Special Education, Remedial and Intervention Programs

In Special Education programs, there are more than three times as many boys as girls. In particular, boys are three times more likely to be identified as Attention Deficit Hyperactivity Disorder (ADHD) as girls. In alternative schools for what is called "social, emotional or behavioral difficulties," there are more boys than girls. In school-based remedial programs, more boys were identified than girls. It is apparent that specialized programming is characteristically dominated by boys. There is a great deal to learn regarding classroom and school practices and the impact on learning for boys and girls. Traditional approaches and solutions to educational dilemmas will require responsible and informed educators for the future.

Gendered School Subjects

Findings show that there are patterns in course-taking behaviors in boys and girls. The ACT, PSAT, SAT results and the participation rates in AP courses revealed that language arts and social studies appeared to be a more female province, while computer science, economics, sciences (especially physics and chemistry) appeared to be a male province. There appears to be more boys enrolled in "basic" or "intervention-like" classes with less boys enrolled in advanced English and literature subjects.

It is a widely-held belief that boys enrolled in the 'maleness' of sciences, computers, and economics and the "femaleness" of language arts and social studies may be a lack of female role models in science, computer and economics and of male role models in language arts and social studies. Therefore, raising the status of teaching in order to attract more people into the profession may be helpful, thus providing male role models for language arts and social studies and to attract more women into sciences and math profession, hence providing female role models for girls.

In England and Wales, the National Curriculum was introduced to reduce many gender inequalities in subjects. In most of the mainstream school subjects, the gap between males and females entry is less than 5% (Arnot et al, 1998). The National Curriculum thus compels girls into mathematics, science, and technology. As the Graduation Standards are implemented in Minnesota public schools, the minimum requirements may need to be established to reinforce students' participation in core subjects, thereby reducing the gender gap patterns in course-taking behaviors.

Gendered Classroom Environment

Females are more engaged in school and classroom learning. Girls tend to work hard, receive higher grades and more recognition from their schools and teachers. On the other hand, boys are between three and four times as likely to be suspended as girls. Boys have more incidents of ill-disciplined behaviors, and risk-taking behaviors. Because boys are generally more impulsive a boy gets into far more trouble in class and in school. The kind of classroom discipline that works for girls—often inconsistent at times, seemingly friendly, and in general, lacking profound authority—does not work so well for many boys in their middle or early high school years.

Findings and Considerations for Practice

This study, in general, demonstrates that middle or high school boys now lag behind girls on many measures of academic performance, such as social studies, linguistics and literature, and social well-being, while girls have made great progress and caught up with boys in mathematics and science. However, few differences were found in developmental cognitive abilities in the verbal skills between boys and girls. Even the average achievement between boys and girls was similar, the distributions, however, were different. A disproportionate number of males performed at the lowest-achieving level while a disproportionate number of females performed at or above the highest-achieving level. At the high-achieving level and upper grades, however, male average achievement appeared to be higher than female achievement, although the number of males in this level is much less.

In the secondary schools, females were clearly more representative on the A Honor Roll and received better grades and more awards than males. Also, there were gender differences in what boys and girls participated in for curricular and extracurricular activities. More females participated in Advanced Placement language arts and social studies courses and took AP tests, while more males participated in AP courses and tests in computers, sciences (particularly chemistry and physics) and economics.

It also appeared that more boys, including elementary-age and secondary-age boys, receive suspensions, were diagnosed as learning disabled, and were represented in greater numbers in alternative programs, remedial and intervention programs, and special education services.

In addition, this study shows that gender differences appear to start as adolescence begins, in particular, in grade eight or nine, and widens during the upper grades. In general, there were few gender differences in areas such as achievement, performance, effort, and risk-taking behaviors in elementary students.

Results from a variety of surveys suggest that females tended to be more engaged than males while in middle and high school. More females reported spending more time on their homework, receiving higher grades in classes, using their time more constructively in music and spiritual activities, reading for fun, or engaging in volunteer work more than their male peers. Older adolescent males consistently showed more risk-taking behaviors than females such as violence, and substance abuse. Although these risk-taking behaviors increased for both boys and girls, as students became older, boys showed a greater increase.

Finally, comparison of statewide and national data mirrored Edina Public School District findings. Gender differences are also apparent in important educational attainments such as high school completion and college attendance. Prior to the 1980s, the number of females was less than or equal to the number of males completing high school and entering college. Subsequent to 1990, the educational attainment of females was higher than males nationally.

In order to verify and interpret the quantitative results, findings were discussed with teachers and school/district administrators. Edina educators generated following considerations and recommendations for educational practices, instruction strategies and policies for improving educational systems which meet both boys and girls' needs.

- 1. Attract both male and female teachers all areas of education to provide role models for both genders.

 This provides all children the opportunity to better understand and experience intelligence and behavioral learning styles from men and women.
- 2. Initiate professional development for educators and parents at all levels of education. Gender differences appear to gather momentum around late grade 5 through high school. Focus on early-to-late middle schooling years during adolescence due to the gender differences onset in early secondary schooling years. Support teaching practices that pay attention to gender learning styles socially, intellectually, emotionally, and physically. Support and fund professional staff development that recognizes male and female brain differences. Devote training time for staff to explore their classroom practices while opening their minds to document evidence of gender differences that influence learning.
- 3. Engage high school students, parents, and educators in dialogue about content of course material at the high school level. Share data with students, parents, and staff and conduct focus groups that engage individuals in new ways to approach entrenched behaviors. Integrate into professional development efforts to deliberately examine how course content and instructional materials may be gender specific or gender biased.

- 4. Using the data, engage in strategic planning that includes information and communication. Attend fiscally and resourcefully to school and classroom decisions that affect boys and communication. Attend fiscally and resourcefully to school and classroom decisions that affect boys and girls in areas specifically, such as honor rolls, recognition of academic achievement, and adult expectations and traditionally held perspectives on learner performances.
- 5. Conduct professional development and apply brain-based research that gives attention to understanding innate gender differences.
- 6. Pay attention to the socializing culture in schools and classrooms. It is plausible that adult expectations and actions support traditionally held beliefs.
- 7. Consider innovative classroom arrangements that customize teaching and learning to meet the unique needs of boys and girls.
- 8. Invite and consider the use of dads, grandfathers, big brothers to school and to classrooms.
- 9. Design mentor programs for both boys and girls. Focus on the unique characteristics of learners. Coach, tutor, and sponsor individual students based on each individuals specific interests and goals.
- 10. Don't confuse discipline with "breaking the spirit" of youth. Be careful how students are reprimanded and counseled.
- 11. Consider educational alternatives to suspension from school. Boys need to be in the classroom and in school.
- 12. Conduct student to student, girls to boys dialogues and allow the students to ask the opposite gender:
 - What are the conflicts and questions we have with each other?
 - What do we want in the way of behavior and understanding from one another?
 - What do we appreciate or admire about each other?
- 13. Continue to explore and find effective ways to support academic engagement on the part of all students, especially boys. Consider summer school, after and before school options. Continue to support programs at school that capture and help nurture boys and girls separately and collectively.

- 14. The models of best practice are multiple and complex, yet very attainable for educators and communities. Know that this is pioneer work; so involve other school districts in solutions. Engage in information sharing seminars with other school districts.
- 15. Overall, keep expectations high for all students and communicate that regularly to them!

In addition, the literature suggests that gender, along with 'race', class, disability, sexuality and age, has a substantial effect on the ways in which children negotiate their personal relationship between academic achievement, school cultures and home and peer culture. Better understanding gender research may help us plan toward a more effective set-of-solutions for improving student performance.

As researchers and educators, we acknowledge the differences among students and strive to understand both gender groups and serve them responsibly. We hope this study not only provides evidence of gender differences that may influence student learning and development, but also suggests a variety of questions for future research and implications for practical teaching and learning. It is hoped that educators will gain a more in-depth understanding of student learning and gender differences and the implications for teaching and learning practice.

Notes

- 1. Laura Waldon, Edina school district releases results of gender study. Edina Sun Current, May 8 2002. Katherine Kersten, Now girls have the advantage in school. Star Tribune, May 22, 2002
- 2. Edina Gifted Education Services Program: This service identifies the educational needs of all students on an ongoing basis. Our goal is to advocate for students with outstanding gifts or talents and provide rigor and challenge in response to their individual needs. See the detailed online information at http://www.edina.k12.mn.us.
- 3. Success Center: This program is one of the remedial instructional services that the Edina Public Schools provides for low-achieving students. One hour is provided before or after school for students to increase their academic achievement.
- 4. Achievement Level Test (ALT): ALT is an assessment instrument that is administered in the Edina Public Schools at Grades 2 through 8 in reading and mathematics. See the detailed online information at http://www.edina.k12.mn.us.
- 5. Minnesota Comprehensive Assessments (MCAs): These tests are given at the third, fifth and tenth grade levels to evaluate student progress on the Preparatory Standards and to measure the success of schools and districts in improving achievement over time.
- 6. Basic Standards Tests (BSTs): The Minnesota Basic Standards Tests (BST) measure if a student has learned the basic skills needed to live and work in today's society. Students must pass tests in reading, mathematics and writing to show they meet the Basic Standards and in order to be eligible to graduate from a Minnesota public high school. The reading and mathematics tests are first given in grade 8 and the written composition test is first given in grade 10.
- 7. PLAN: PLAN assessment is given to all students in grade 10 and provides information for academic achievement, career planning, instructional support and program evaluation for Grade ten students. PLAN test results are reported in a scale score ranging from 1 to 32. See http://www.act.org for detailed information.
- 8. ACT Assessment Program: The ACT assessment program measures educational development and readiness to pursue college-level coursework in English, mathematics, natural science, and social science.
- 9. Advanced Placement: Advanced Placement (AP) gives highly motivated students an opportunity to take college-level courses and exams while still in high school. There are now 32 different AP courses to choose from, in 18 different subject areas, offered by approximately 14,000 high schools worldwide.
- 10. PSAT: The PSAT assesses student knowledge and skills developed through years of study in a wide range of courses and experiences outside the classroom. Although the PSAT and the SAT Program tests are not directly related to a specific high school curriculum, they are developed to reflect the kinds of academic experiences that teachers consider important.
- 11. SAT: The SAT and ACT are both widely-used admission tests. Many colleges accept either one, but some require one or the other. The SAT measures verbal reasoning, critical reading, and math problem solving skills. It tells how well test takers uses the skills and knowledge they have learned so far, both in and out of school.

- 12. Minnesota Student Survey: This survey was administered by the Department of Children, Families and Learning of the Minnesota State. This survey was designed to address the issues that confront youth and to evaluate trends over time. It has been administered every 3 years since 1989. Results can be used to evaluate and improve prevention efforts.
- 13. Developmental Assets Survey: The Developmental Assets Survey: A Profile of Your Youth was developed by the Search Institute. The asset framework represents a common core of developmental building blocks crucial for all youth. The survey results show the extent to which Edina students experience these assets and how the assets relate to their behavior. Usually the developmental assets are grouped into two major types. External assets are the networks of support, opportunities and people that stimulate and nurture positive development in youth. Internal assets are the young person's own commitments, values and competencies.
- 14. Edina Student Opinion Survey: Beginning in 2000, the Edina Public Schools conducted opinion surveys of all students, school staff, and parents. The surveys were designed to examine feelings and perspectives from students, staff, and parents regarding their educational experience with the Edina Public Schools.
